Projections of the Population of Texas and Counties in Texas by Age, Sex and Race/Ethnicity for 1990-2025

From

The Texas State Population Estimates and Projections Program
Texas Department of Commerce

Prepared by

Department of Rural Sociology
Texas Agricultural Experiment Station
Texas A&M University System

December 1988

The Texas State Population Projection Program's projections of the population of Texas and of each county in Texas were prepared by personnel from the Department of Rural Sociology in the Texas Agricultural Experiment Station in the Texas A&M University System under contract to the Texas State Data Center Program in the Texas Department of Commerce. These projections, like all projections, involve the use of certain assumptions about future events that may or may not occur. Users of these projections should be aware that although the projections have been prepared with the use of complex and detailed state-of-the-art methodologies and with extensive attempts being made to account for existing demographic patterns, they may not accurately project the future population of the State or of particular counties in the State. These projections should be used only with full awareness of the inherent limitations of population projections in general and with particular and detailed knowledge of the procedures and assumptions delineated below which characterize the projections presented in this report.

The Texas State Population Projection Program's projections are of the population of the State and of all counties in the State for each year from 1990 through 2025. They are by single years of age for ages 0 through 75 years of age or older for males and females in each of four racial/ethnic groups--Anglos, Blacks, Hispanics, and persons from Other racial/ethnic groups (the terms Hispanic and Spanish origin are used interchangeably throughout the report). These four groups have been configured so that the total population is the sum of Anglos, Blacks, Hispanics, and persons of Other racial/ethnic groups.

This summary describes the methodology used in deriving the projections, delineates the basic assumptions underlying the alternative projection scenarios, and describes the output available from the projection process. It begins with a relatively detailed description of the methodology and then discusses the bases for, and the assumptions used in, creating the alternative projection scenarios. It concludes with a description of the outputs available from the projection process.

Projection Methodology

The projections were completed using a cohort-component projection technique. As the name implies, the basic characteristics of this technique are the use of separate cohorts--persons with one or more common characteristic--and the separate projection of each of the major components of population change--fertility, mortality and migration--for each of the cohorts. These projections of components for each cohort are then combined in the familiar demographic bookkeeping equation as follows:

$$P_{t_2} = P_{t_1} + B_{t_1-t_2} - D_{t_1-t_2} + M_{t_1-t_2}$$

Where: P_{t_2} = the population projected at some future date $t_1 - t_2$ years hence

P_{t_1} = the population at the base year t_1

$B_{t_1-t_2}$ = the number of births that occur during the interval $t_1 - t_2$

$D_{t_1-t_2}$ = the number of deaths that occur during the interval $t_1 - t_2$

$M_{t_1-t_2}$ = the amount of net migration that takes place during the interval $t_1 - t_2$

When several cohorts are used, P_{t_2} may be seen as:

$$P_{t_2} = \sum_{i=1}^{n} P_{c_i,\ t_2}$$

Where: P_{t_2} is as in the equation above

$P_{c_i,\ t_2}$ = population of a given cohort at time t_2

and $P_{c_i,\ t_2} = P_{c_i,\ t_1} + B_{c_i,\ t_1-t_2} - D_{c_i,\ t_1-t_2} + M_{c_i,\ t_1-t_2}$

Where: all terms are as noted above but are specific to given cohorts c_i

In this, as in any other use of the cohort-component technique at least four major steps must be completed:

1. The selection of a baseline set of cohorts for the projection area or areas of interest for the baseline time period (usually the last census and for other dates for which detailed base data are available)

2. The determination of appropriate baseline migration, mortality, and fertility measures for each cohort for the baseline time period

3. The determination of a method for projecting trends in fertility, mortality and migration rates over the projection period

4. The selection of a computational procedure for applying the rates to the baseline cohorts to project the population for the projection period

Each of these steps as performed for the Texas State Population Projections Program's projections are briefly discussed in the pages which follow.

Selection of Baseline Cohorts

The baseline cohorts used in the projections are single-year-of-age cohorts for males and females of Anglo, Black, Hispanic and Other

racial/ethnic groups extracted from Summary Tape File 2 from the 1980 Census of Population and Housing. Population data for 1980 were used as the starting base because they provide the last complete count information available and are not subject to the estimation errors in all post-1980 data. However, because of the relatively extensive period since the 1980 Census and given the availability of detailed estimates by age, sex, and race/ethnicity for 1986 from the Texas State Population Estimates Program, it was possible to update the baseline to 1986. The procedures described below which were completed for the 1980 baseline, ensured the integrity of both the 1980 and 1986 baseline data. The projections (1990-2025) were made using the adjusted (as described below) 1986 data as the base.

Because the 1980 data by single years of age and sex were readily available by the racial categories of White, Black and several other racial groups or by Spanish origin or Non-Spanish origin but not for the racial/ethnic categories of Anglo, Black, Hispanic and Other, it was necessary to construct a baseline cohort of the Anglo, Black, Hispanic and Other populations by subtracting the number of Spanish-origin persons by age, sex and race from the total population by age, sex and race. The cohorts thus produced are Anglos (composed of White Non-Spanish-origin persons), Blacks (consisting of Black Non-Spanish-origin persons), Hispanics (Spanish-origin persons of all racial and ethnic groups), and Others (composed of persons of other racial and ethnic groups who are not of Spanish origin). So constructed, the sum of populations in the four racial/ethnic groups of Anglo, Black, Hispanic, and Other are equal to the total population.

In addition to forming the distinct and summative racial/ethnic categories, it was also necessary to adjust the base population for "special populations". Special populations are populations who reside in an area, usually in institutional settings, who do not generally experience the same demographic processes over time as the indigenous population in the area. Rather, they tend to come into and leave an area at fixed intervals. Examples of such populations are college populations, prison populations, military base populations, and other persons in institutional settings. Because their movement into and out of an area is a function of events (e.g., enrollment, graduation, incarceration) which are not determined by local socioeconomic conditions, special populations must be removed from the base populations of projection areas before birth, death and migration rates are applied to the base population. If special populations of substantial size are not removed, they will create age and other distortions in the population that will remain in the population through the cohort aging process and create inaccuracies in the projections. Special populations are, therefore, generally removed from the cohort base, the base cohorts projected forward and a separate projection of the special population for the projection date is added to the projected base cohorts to obtain the projection of the total population.

In Texas, several special population groups are especially large and must be removed from base populations. These are college and university populations, state prison populations, military populations, and populations in other State institutions. In the projections presented here, each of these groups was removed from the base population of the

counties in which they are located by subtracting these special populations from the 1980 population reported in the Census for these counties. Since these special populations must be subtracted from base populations that are age, sex and race/ethnicity specific, it was necessary to obtain age, sex and racial/ethnic detail for the special populations. This was done for the college populations by obtaining information on college enrollment for each public college and university in the State for 1980 by age, sex and race/ethnicity from the Texas Higher Education Coordinating Board, and subtracting that population from the base population in each county with such an institution. For prisons, information on the age, sex and race/ethnicity of prisoners in each institution in 1980 was obtained from the Texas Department of Corrections. For other institutions, information on age, sex and race/ethnicity was not readily available. However, data were available in a specialized census file (U.S. Bureau of the Census, 1984a) on persons in the military and in other institutions by age, sex and race/ethnicity. Data on the total military population in 1980 and on the populations in other institutions collected as part of the Texas State Population Estimates Program were used as the base populations for these institutions, and these populations were removed from the base population by age, sex and race/ethnicity on the basis of the proportion in each age, sex and racial/ethnic group in these special populations in 1980. Given the distributions of the special populations by age, sex and race/ethnicity, it was then possible to subtract the special populations from the baseline 1980 Census cohorts to obtain a baseline set of cohorts free from the influence of special populations. These procedures for baseline cohorts were completed for all counties in the State. As noted below, these baseline cohorts are projected forward and projections of special populations for the projection years are added to the projections for the baseline cohorts to obtain projections of the total population. The 1986 base population was derived by projecting the 1980 base forward to 1986 using assumptions that produced a total population equal to the 1986 population estimate. However, because more detailed data on special populations have been acquired since the release of the 1986 estimates, and used to adjust the 1980 base, the detailed age, sex and race/ethnicity distributions of the 1986 county base populations used for these projections differ slightly from those in the previously published estimates for 1986. The revised 1986 population estimates by age, sex and race/ethnicity used as the base for these projections are included as standard output with the projections.

Determination of Baseline Fertility, Mortality and Migration Rates

Fertility Rates

Age, sex and race/ethnicity specific fertility rates were computed using births by age, sex and race/ethnicity and place of residence of the mother. Because of the potential for large proportional year-to-year fluctuations in the number of births, especially for small population areas, the numerators for such rates are the average number of births for 1979, 1980 and 1981 for mothers in each age, sex and race/ethnicity group. Birth data to compute the rates were obtained from the Texas Department of Health and data on women by age (10-49 years) and race/ethnicity were

obtained from the 1980 Census of Population.

Birth data from the Texas Department of Health are available for Whites, Blacks and Other racial/ethnic groups and for Spanish-surname persons. For the projections presented here, rates for Whites were used for Anglos, Black rates for Blacks, White rates for Other racial/ethnic groups (because computed rates for the Other racial/ethnic group are often unstable due to small populations in some counties) and Spanish-surname rates for Hispanics. Because these rates were computed using Anglo, Black, and Hispanic racial/ethnic groups as denominators but with numerators that were births for Whites and persons of Other racial/ethnic groups, Blacks, and persons with Spanish surnames, some disjunctures in rates may appear (the Texas Department of Health birth data, however, are in mutually exclusive categories of White, Black, and Spanish surname so that the disjunctures are partially mitigated). These distortions are generally minor, however, and since no procedure is available to resolve this potential problem, it was necessary to use rates employing slightly different population bases in their numerators and denominators.

Mortality Rates

To obtain baseline mortality measures, survival rates by single years of age, for both sexes and for each of the racial/ethnic groups were needed. Life table survival rates for Whites and Non-Whites were computed using 1979-81 life tables derived from Texas Department of Health mortality data. Rates for Whites were assumed to apply to Anglos and persons in the Other racial/ethnic category and rates for Non-Whites were used for Blacks. Survival rates for Hispanics in Texas were derived from life tables obtained from the Population Research Center at the University of Texas at Austin.

Migration Rates

Migration is the most difficult component process to project and for which to obtain baseline rates. For the Texas State Population Projection Program's projections, rates were derived using the procedures developed by Hwang et al. (1985) to produce net migration estimates by age and sex for Whites and Non-Whites in Texas for 1970-80. An evaluation of the rates from Hwang et al. (1985) relative to vital statistic data, however, indicated that although White rates could be assumed to apply to Anglos and persons in the Other racial/ethnic group, and Non-White rates to Blacks, Hispanic migration patterns were likely not to be adequately represented by either the White or Non-White rates. A detailed analysis also indicated that it was not possible to develop reliable rates for each of the four groups of Anglos, Blacks, Hispanics and persons from the Other racial/ethnic groups because of differences in definitions of key terms and groups between 1970 and 1980. It was possible, however, to construct a set of age and sex specific net migration rates for Hispanics that were reasonable in light of other demographic indicators. This required that 1970 base populations for Hispanics be reconstructed.

To reconstruct the 1970 base population by age and sex for the Hispanic population for each county, fifth-count 1970 Census data for Spanish-American persons (the category most similar to the 1980 designation of Spanish origin) by age and race were used (U.S. Bureau of the Census, 1971). Given such data, it was necessary both to adjust the total 1970 Spanish-American population to be similar to the category of Spanish origin in 1980 and to obtain race detail for the Spanish-American population in 1970. These were obtained by first using the ratio of Spanish-American persons to Spanish-origin persons in the 1980 Public Use Microdata Sample (PUMS) (U.S. Bureau of the Census, 1983) for PUMS areas and adjusting 1970 fifth counts of Spanish-American persons in each county by the ratio of Spanish-American to Spanish-origin persons in 1980 in the PUMS area of which each county was a part. The proportion of the 1980 Spanish-origin population in each race group in each county was then assumed to apply to the adjusted 1970 fifth-count population of Spanish American persons by age and sex in each county. This application resulted in a 1970 base population of Spanish-American persons by age, sex, and race. Although this 1970 Spanish-American population is not absolutely comparable to the 1980 Spanish-origin population (because the Spanish-American population in 1970 was determined by language used at home and Spanish surname, while Spanish origin in 1980 was determined by self-identification), an analysis of these data suggests that the values are reasonable in light of birth, death, and other data for 1970 and 1980.

Given data on the 1970 and 1980 populations by age, sex and race, the basic procedures for computing net migration rates using the residual method of computation (as outlined in Hwang et al., 1985) were then used to compute annual net migration rates based on 1970 to 1980 migration patterns for both Hispanic males and females. Because data on Spanish-American persons for 1970 could not be obtained for single years of age, net migration rates for 5- and 10-year age groups were reconstructed for the White and Non-White categories as well and values for Whites, Non-Whites and Hispanics disaggregated into single-year age groups for use in the projections. In sum, then, White rates were assumed to apply to Anglos and persons in the Other racial/ethnic group and Non-White rates to Blacks. The constructed Hispanic rates were used for Hispanic populations.

Projection of Trends in Fertility, Mortality and Migration

Projections of Fertility

To project future rates of fertility, county and State-level projections were assumed to follow national patterns of projected change in fertility as indicated in the Census Bureau's projections of the population of the United States. The rates employed were those projected by the Census Bureau for the total population and for Whites and Blacks (U.S. Bureau of the Census, 1984b) and for the Hispanic population (U.S. Bureau of the Census, 1986). In these national projections, three alternative projections of fertility, cumulating in total fertility rates of 1.6, 1.9 and 2.3 by approximately the year 2025 were employed. These total fertility rates are the sum of a projected set of age and race/ethnicity specific fertility rates which are assumed to change over the projection

period before stabilizing at rates which result in total fertility rates of 1.6, 1.9 and 2.3.

For the projections reported here, single-years of age, sex and race/ethnicity specific fertility rates and total fertility rates for 1980 were computed for counties using the data and procedures described above. The counties' trends in fertility for the projection period from 1980 to 2025 were then projected by determining the national level of total fertility which was most similar to each county's total fertility rate for each racial/ethnic group in 1980 (i.e., whether it was closest to 1.6, 1.9 or 2.3) and assuming that the county's future fertility would follow the national trend for the rate that was closest to its 1980 rate.

Specifically, this involved computing a ratio between the age and race/ethnicity specific birth rate for each age and racial/ethnic group for each county and the comparable national age and race/ethnicity specific birth rate for 1980. This ratio for each age and race/ethnicity specific birth rate for each county was then multiplied by the projected national rate for each of the projection years, with the national rates used in the multiplication being that set which produced a total fertility rate closest to each county's 1980 total fertility rate for each racial/ethnic group. The identical procedure was used for the State projection, but the rates employed were ones computed for the State as a whole. This procedure does not result in county and State rates becoming identical to those for the Nation, but causes the county and State rates to show the same patterns of change over time as the change in the rates projected for the Nation.

The use of these national trends generally produce reductions in fertility for counties in the State and the State as a whole. For example, as a result of the use of these trends at the State level, rates for Anglos are reduced from a total fertility rate of 1.79 in 1980 to 1.64 in 2025 under a national rate of 1.6, increased to 1.95 under a national rate of 1.90 and increased to 2.35 for 2025 under a national scenario of 2.3. The comparable changes for Blacks were from 2.36 in 1980 to 1.82, 2.16 and 2.61, and for Hispanics from 3.05 in 1980 to 2.61, 2.94 and 2.96 respectively for the three rates by 2025.

Given 1980 fertility rates in the State and the assumption that fertility will decline over time, the scenarios employed in the final projections for the State for Anglos (and Others) was the trend toward 1.6, for Blacks the trend toward 1.9, and for Hispanics the trend toward 2.3. Under these trends, the total fertility rates for the State for the three groups reduce to 1.64 for Anglos and Others, 2.16 for Blacks, and 2.96 for Hispanics by 2025. The small decline projected for Hispanic fertility reflects the fact that it is not clear whether Hispanic fertility has declined, but clear patterns of decline are evident in fertility patterns for other groups (U.S. Bureau of the Census, 1986). The process of selecting appropriate rates for trending fertility was repeated for each racial/ethnic group for each county so that the trends for individual counties vary markedly from State-level patterns in some counties, but are reflective of existing fertility levels in each county in 1980.

Projections of Mortality

The projections of mortality for the projection period were made in a similar manner to the projections of fertility with county and State rates being assumed to follow national trends for the projection period and 1980 county and State age, sex and race/ethnicity survival rates being ratioed to national age, sex and race/ethnicity specific survival rates. The national rates were those obtained from the same source as noted for fertility (U.S. Bureau of the Census 1984b, 1986).

Unlike for fertility, however, it was not deemed necessary to use alternative trends in mortality over time. As a result, all county and State rates were ratioed to a single national projection. The national mortality projection used was the middle mortality projection (U.S. Bureau of the Census 1984b, 1986). This projection for the nation results in a life expectancy at birth of 73 for males and 81 for females in 2000, increasing to 74 for males and 81 for females in 2025. Since both Texas and the Nation as a whole had life expectancies at birth of approximately 70 for males and 78 for females in 1980 and the differences in total life expectancy under the alternative assumptions are relatively small (the low assumption gives a life expectancy at birth 2 years higher and the high mortality assumption a life expectancy 2 years lower than the middle assumption), the use of a single middle-range set of mortality assumptions was deemed appropriate. In addition, because total mortality levels for counties are quite similar after controlling for age, sex and race/ethnicity and the number of deaths by single years of age is so small in many counties that reliable county-level rates cannot be computed, State survival rates ratioed to the national rates were assumed to apply to all counties.

Projections of Migration

The migration component is the most difficult to project. For the Texas State Population Projection Program's projections, the age, sex and race/ethnicity specific net migration rates (calculated in the manner described on page 8 and 9) were used to arrive at three alternative scenarios of growth (described in the following pages) by systematically altering the assumptions related to the entire set of age, sex, and race/ethnicity specific net migration rates. No attempt was made to develop alternative scenarios for specific age groups or to formulate scenarios using different assumptions for each of the racial/ethnic groups. Although several alternative scenarios were examined, the number that could be usefully employed in the projections was limited to three.

Special Considerations in the Projection of Component Rates

The computation and projection of fertility and migration rates at the county level was sometimes problematic for counties with small population bases. Given the use of 4 racial/ethnic groups, 2 sexes and 75 age groups, a total of 600 cells of data were employed for each county. In counties with small populations in which either the baseline population used as the

denominator to compute rates and/or the number of events used in the numerator (i.e., births or net migrants) was too small to produce reliable and reasonable rates, it was necessary to develop a means of obtaining reasonable rates. To identify these counties, each county's rates for each age, sex and racial/ethnic group was examined relative to rates for the Council of Government region in which it was located and for the State. Counties were deemed to have unreasonable age-specific fertility rates if they exceeded 0.25 for any single-year age group or were 0.0 (rates that allows up to 25 percent to give birth per year). Unreasonable migration rates were those in which per-person-per-year rates were 0.10 or greater (a rate that allows up to 10% migration per single-year age group per year) or if no migration (a migration rate of 0.0) was evident. Since migration rates can have either positive or negative values, this allowed migration rates to vary between -0.10 and 0.10 per person per year for each age, sex and race/ethnicity cohort. The counties identified as having problematic rates were largely nonmetropolitan, most with relatively small populations. Relatively few metropolitan central city and suburban counties had problematic rates.

In order to obtain reasonable rates for counties for which problems had been identified, rates for larger groupings of areas with characteristics similar to the counties for which alternative rates were necessary were used to develop homogenous groupings of areas. All counties within Council of Government (COG) regions were thus divided into four groups--metropolitan central city counties, metropolitan suburban counties, nonmetropolitan counties that are adjacent to metropolitan counties, and nonmetropolitan counties that are not adjacent to metropolitan counties. The rates for these groupings were used because analysis indicated that the rates for these 4 types show substantial homogenity across areas within each grouping but substantial differences among the groupings. Fertility and migration rates were completed for each of these four county types within each region and for the four types for the State as a whole (by using the aggregate populations of counties within each type within each region and/or the total State population by type).

For counties with problematic rates, rates for the county type of which the county was a member for the COG region where the county was located were substituted only for the problematic rates for those racial and ethnic groups for which the rates computed with the county's own population data were deemed to be problematic. For a few regions for a few racial/ethnic groups, even the COG rates were problematic. In such cases, the State rate for the county type was substituted for the county rate. It is important to stress that this procedure does not result in the rates for all nonmetropolitan counties or rates for all age and sex groups for a given racial/ethnic group being replaced by regional or State averages. Rather, replacements are made for only those rates for age, sex, and racial/ethnic cohorts within counties which had problematic values. Even in small counties, rates were generally substituted for only a few age and sex groups for a single racial/ethnic group. Thus, local differentials in demographic patterns are maintained in the population projections.

Although the procedure described above was generally adequate for rate adjustments, the review of the provisional projections indicated that for use in many counties, the migration data for Hispanics based on the

patterns of the 1970s were problematic. It often resulted in substantially higher rates of net migration for Hispanic males than for females, causing an imbalance that could not be expected to continue over the entire projection period. The ratio of Hispanic female rates relative to male rates for each age were adjusted to be no smaller than the ratio of male to female rates at the COG and State levels within county types (i.e., metropolitan central city, metropolitan suburban, nonmetropolitan adjacent, and nonmetropolitan nonadjacent). If the ratio of Hispanic male to Hispanic female migration rates for a county for any age exceeded the ratio for the COG, its rate for that age were replaced with that for the COG. If the COG's rate for the county type was still problematic, the rate for that age for that county type for the State as a whole was substituted for the county rate. The use of this procedure resulted in substantially more balanced sex ratios for male and female Hispanics in the final projections.

The Computation and Selection of Future Projection Scenarios

In this section, both the assumptions underlying the projection scenarios and the final computational procedures are described. For both, the emphasis is placed on the logic underlying the scenarios and procedures rather than on the detailed computational processes. Those interested in greater detail may consult several readily available references on the subject (Murdock et al., 1987a; Pittenger, 1976) or may contact the personnel involved in the Projection Program in the Department of Rural Sociology at Texas A&M University.

The Projection Scenarios

Three projection scenarios which produce three alternative sets of population values for the State and each county are presented in these projections. These scenarios assume the same set of mortality and fertility assumptions in each scenario but differ in their assumptions relative to net migration. The net migration assumptions made are derived from 1970-80 patterns which have been altered relative to the population trends of the 1980s (see Murdock et al., 1987b). This is done by systematically and uniformly altering the adjusted (as noted above) 1970-80 net migration rates by age, sex and race/ethnicity. The scenarios so produced are referred to as the zero migration (0.0) scenario, the 1970-80 (1.0) scenario, and the middle-range (0.5) scenario.

The Zero Migration (0.0) Scenario

The zero scenario is a scenario which assumes that inmigration and outmigration are equal (i.e., net migration is zero) resulting in growth only through natural increase (the excess or deficit of births relative to deaths). This scenario is commonly used as a base in population projections and is useful in indicating what an area's indigenous growth (growth due only to national increase) will be over time. In general, this scenario produces the lowest population projection for counties with

historical patterns of population growth through net inmigration and the highest population projection for counties with historical patterns of population decline through net outmigration.

The 1970-80 Migration (1.0) Scenario

The 1970-80 scenario assumes that the trends in the age, sex and race/ethnicity net migration rates of the 1970s will characterize those occurring in the future of Texas. This period was an era of very rapid and unprecedented population growth in the State and is judged to be the highest rate of growth likely to be experienced by areas given the overall combination of past and recent population patterns experienced in the State (Murdock et al., 1987b). Although higher rates of net inmigration were experienced during the 1980-82 time period, nearly all counties in the State had rates of growth substantially below even the 1970-80 rates by the mid-to-late 1980s, and it is deemed unlikely that most areas in the State will be able to return to higher rates of growth than those of the 1970-80 period in the near future. Thus, this scenario produces the highest projected populations for those areas which had net inmigration during the 1970s. For counties that continued to experience net outmigration during the 1970s, their 1970-80 net outmigration rates were, in nearly all cases, substantially lower than in previous periods indicating that the 1970s was a period of increased population retention, although increased retention did not compensate for overall population loss. As a result, although this scenario does not result in population increases for counties with historic patterns of decline, in most cases it reduces the rate of decline and is, in relative terms, a scenario of improved population growth.

The Middle-Range Migration (0.5) Scenario

The middle-range scenario has been prepared as an approximate average of the zero and 1970-80 scenarios and is expected to be the most likely scenario of population growth for most counties--at least for the immediate future. It assumes rates of net migration one-half of those of the 1970s. The reason for placing emphasis on this scenario is that most counties in the State are experiencing rates of population growth substantially below the levels of growth of the 1970s and many are, in fact, at zero or have negative rates of growth, according to 1987 population estimates (the most recent estimates available at the beginning of December of 1988). It is believed, however, that population growth rates will begin to recover slowly, if the economic climate of the State recovers sufficiently. A scenario which projects rates of growth that are approximately an average of the zero and the 1970-80 scenarios is one that suggests an increase in growth from present levels--but slow and gradual growth. In addition, this scenario uses net migration rates that are one-half of the magnitude of those for 1970-80, and the use of such rates has been found to produce reasonable projections of future populations in an earlier analysis (Murdock et al., 1988).

Although each of these projection scenarios is based on reasonable alternatives of population growth, users of these data should be aware that projections are inherently speculative and that no assurance can be

provided that these scenarios will correctly predict or even bracket the actual level of future population growth in the State. In addition, because of the variability of population patterns among the counties in the State, users should be aware that the scenarios are likely to be more accurate for some areas than for others.

Computation of Future Populations

Given the projected rates and scenarios noted above, the computation of the projected population was completed using standard cohort-component techniques as described above with all computations being completed on an individual year and age basis for each sex and racial/ethnic group. Base population values for 1986 were used as the starting values and populations were projected for the years from 1990-2025. Because of the need to ensure that the sum of county projections produces reasonable future populations for the State as a whole, the State's future population by age, sex and race/ethnicity was first independently projected under each of the scenarios described above. County base cohorts were projected to the projection date and projected special populations added to the projected base populations. Projected populations of colleges and universities for future years were taken from projections by the Texas Coordinating Board for Colleges and Universities (1988) and military and other institutions were assumed to remain at their 1986 levels. The State-level projections were then used as control totals for the sum of county projections for each age, sex and racial/ethnic group. The projections so produced and controlled for each scenario are those provided here as projections of the population of the State and of each county in the State.

Data Available from the Projections

The data produced in the process of completing the projections presented here and the data summarizing the projections themselves are extensive. The amount of data available for the State and each of 254 counties for 3 scenarios of growth, for each year from 1990 through 2025 for each of 75 age groups for 2 sexes and 4 racial/ethnic groups is too voluminous to be provided in its entirety in printed form. Thus, data are provided in several different forms to address the needs of different user groups.

This publication describes the projection methodology and provides an appendix showing the base populations for the State for 1980 and 1986, and the base rates for fertility, mortality and migration for 1980 for the State. Due to the volume of data involved, rates for other years and areas will be provided only on request.

Because of the volume of data, printed data are provided only on request. The fully detailed projections of the population in each age, sex and racial/ethnic group for each county and the State for each year from 1990 through 2025 are available either on computer tape for the State and all counties in the State or on floppy disks for the State and counties within Council of Government regions. Users can receive data on floppy disks by simply specifying the Council of Government regions for which they

wish to obtain data. In addition, data on floppy disk for individual counties can be provided on request.

To obtain the printed copy of this report, users should contact:

Ms. Susan Tully, Coordinator
Texas State Data Center
Texas Department of Commerce
P.O. Box 12728, Capitol Station
Austin, Texas 78701
(512) 320-9683

Persons interested in obtaining computerized forms of the data should contact:

Texas Population Projections Program
Department of Rural Sociology
Special Services Building
Texas A&M University
College Station, Texas 77843-2125
(409) 845-5115

All data are available on a cost-recovery basis from the above agencies.
